February 2004

We wish to thank Alec Crystal, Giovanna Nicodano and Dylan Thomas for their helpful comments. We also thank Karen Simhony-Boniell for assistance during the data collection process. Special thanks are due to Mark N. Cutis, Jaakko P. Karki, Fukuyoshi Kikunaga, Amos Rubin, and Constantine Thanassoulas for their detailed description of the workings of the primary market for international bonds. A. Melnik thanks the visiting fellow program at ICER in Torino for its hospitality while part of this work was conducted. Maela Giofre' provided excellent research assistance.

Issue Costs in the Eurobond Market: The Effects of Market Integration

Abstract

This study compares the issuance costs of Eurobonds before and after the completion of the Economic and Monetary Union (EMU) in 2002. We find that the introduction of the Euro has significantly reduced the issue cost of Euro-denominated bonds compared with bonds denominated in the legacy currencies. The reduction in issue cost is not due to a decrease in underwriter compensation, but rather to the elimination of underpricing (the difference between the market price after trading commences and the offering price). Underwriter fee has declined substantially after the completion of the EMU, but this decline has been offset by an increase in underwriter spread (the difference between the offering price and the guaranteed price to the issuer), leaving total underwriter compensation unchanged. The EMU is also associated with significant reductions in bond maturity and syndicate size, consistent with its expected effects on liquidity and issue costs in the Eurobond market.

Key words: Eurobonds; issue costs; underwriter compensation; underpricing; EMU

JEL classification codes: G15; G24; G30

1. Introduction

For over 40 years the US dollar has been the currency of choice for international debt contracts. On January 1, 1999, a new currency, the Euro, was created with the aim of replacing the currencies of twelve European countries. Since January 2002, the Euro is used for both retail and capital market transactions in the European Union. Although major European currencies such as the German Mark and French Franc have been used internationally in the past, neither currency approached the international use of the US dollar. With the creation of the Euro, the dollar has a potential rival for the role of the leading international currency. Extant research has examined the role of the Euro in real trade and concluded that the Euro is likely to become a major international currency and favorably impact real trade flows between European countries.¹ The implications of the new currency for debt markets, however, have not been fully explored.

The Economic and Monetary Union (EMU) in Europe is expected to reduce the issue costs of Euro-denominated bonds (compared with bonds denominated in the legacy currencies) for the following reasons. The creation of a uniform currency has eliminated currency risk and expanded investor base, thereby improving liquidity and lowering transaction costs. The EMU has also reduced the reliance of bond underwriters on local expertise, and introduced opportunities for economies of scale in bond issuance. As a result of these changes, the effort and uncertainty associated with pricing and selling Euro-denominated bonds have declined, which is expected to lead to a reduction in bond flotation costs.

¹ See, for example, Portes and Ray (1998), Rose and van Wincoop (2001), Frankel and Rose (2002), and Glick and Rose (2002).

In this study, we compare the issue costs of Eurobonds before and after the completion of the EMU in 2002. We examine three components of issue costs: underwriter fee, underwriter spread (the difference between the offering price and the guaranteed price to the issuer), and underpricing (the difference between the market price after trading commences and the offering price). For the pre-EMU period, we analyze the issue costs of bonds denominated in the US Dollar (USD) and in three of the major currencies that were replaced by the Euro: French Franc, Dutch Guilder and German Mark. For the EMU period, we examine the issuance costs of Euro- and USD-denominated bonds.

We find that during the pre-EMU period the issue costs of bonds denominated in the legacy currencies were larger than the issue costs of USD bonds, primarily due to differences in the extent of underpricing. USD bonds were issued in the primary market at prices close to their market values, while legacy currency bonds were issued at a discount. Total underwriter compensation was only slightly larger for the legacy currency bonds than for USD bonds, although the average values of the two components of underwriter compensation (fee and spread) were very different for the two groups. The mean underwriter fee was almost twice as large for the legacy currency bonds compared with USD bonds, but this difference was almost fully offset by an opposite difference in mean underwriter spread. That is, underwriters charged larger fees for legacy currency issues but guaranteed a considerably higher price relative to similar USD issues. Consequently, the differences in total underwriter compensation between bonds denominated in USD and those denominated in the legacy currencies were small.

Our analysis of the EMU period reveals that the differences in issue costs between the USD bonds and European currency bonds have largely disappeared. Specifically, like USD bonds, Euro-denominated bonds are not underpriced. In addition, the differences in the components of underwriter compensation (fee and spread) between the two groups are much smaller compared with the pre-EMU period. Finally, the issue characteristics of Euro-denominated bonds (e.g., maturity, syndicate size) are similar to those of USD bonds. All these changes are consistent with the expected effects of the EMU.

Interestingly, we find little differences in total underwriter compensation across currency denomination and over time. Underwriter fees vary substantially over our sample period and across currency denomination, but this variation is generally offset by opposite differences in underwriter spread. Focusing on underwriter fee, Santos and Tsatsaronis (2003) conclude that the EMU resulted in a substantial reduction in underwriter compensation. We demonstrate that the reduction in underwriter fee was offset by a similar increase in underwriter spread, leaving total underwriter compensation unchanged. The EMU did cause a reduction in bond issue cost, but this reduction was due to the elimination of underpricing rather than to a decrease in underwriter compensation.

The paper proceeds as follows. In the next section, we describe the institutional features of the Eurobond market and briefly survey some recent developments. In Section 3, we discuss potential implications of the EMU for the issue costs of Eurobonds. Section 4 defines the main variables of the analysis, and Section 5 provides descriptive statistics for the pre-EMU and EMU samples. In section 6 we present the results of multivariate analyses, and we conclude in Section 7.

2. The Eurobond Market

A Eurobond is a debt instrument issued simultaneously to investors in a number of countries, outside the jurisdiction of any single country. Originally, the main borrowers in the Eurobond market were international agencies, sovereign governments of developed countries and major banks. After the mid-80's, high quality corporate borrowers also entered the market. In the mid-90's, corporate borrowers became dominant. Most corporate Eurobonds are issued by firms from the financial services sector. Other important corporate participants, on the supply side, are industrial conglomerates, utilities, and firms from diverse sectors such as food, chemicals and communication equipments. Most of the bonds are issued by entities from highly developed countries such as the US, UK and Netherlands, and about 10% are issued by international agencies such as the European Investment Bank and the International Bank for Reconstruction and Development.² The Eurobond market grew rapidly during the 1990's. For example, Claes, De Ceuster and Polfliet (2002) report that 3,716 issues with total face value of 857.3 billion USD were sold in the primary market during 1999, compared with 1,206 issues totaling 169.7 billion USD nine years earlier.

In general, the credit quality of Eurobonds is very high, as most Eurobonds are rated in the AAA to A range. Only about 5% of the issues receive BBB ratings at the time of issue, and few issues are ranked BB or below. During the 1980's, bonds with initial maturity between five and ten years accounted for more than 50% of the total face value, while issues with maturities between one to five years (over ten years) constituted about

² The statistics in this section were extracted primarily from Claes, De Ceuster and Polfliet (2002), who provide a detailed analysis of the primary market for Eurobonds based on information about 33,024 publicly issued Eurobonds during the period 1980-2000.

15% (35%). In the 1990's, the five-to-ten years category has declined to about 40%, and the one-to-five years category has increased to 30%. Eurobonds are primarily fixed coupon bonds (71%). The remaining bonds are floating rate notes (20%), zero coupon bonds (5%), or convertible bonds (4%).

Fixed coupon Eurobonds are purchased from the issuer by syndicates of investment banks that are formed specially for underwriting purposes on a case-by-case basis. The syndicate structure is typically “flat,” consisting of one arranging (lead) bank and several regular members.³ Banks may operate in some syndicates as leaders and in others as regular members. Since the mid 1990, the number of syndicate members who participate on a regular basis is about two hundreds, although this number has slightly declined in recent years. The lead bank negotiates conditions with the borrower and prepares the necessary documentation.⁴ It usually underwrites a significant amount of the issue, while other members of the syndicate receive the residual allocation. The members purchase the issue according to an agreed sharing formula at the underwritten (guaranteed) price, and resell their share of the issue either to “book registered” customers or to the market. Thus, syndicate members carry a standard underwriting risk; if they cannot sell the entire issue, they have to carry parts of it in their own books until the entire allocation is sold, possibly at lower prices.⁵ In exchange for taking this risk and

³ According to Claes, De Ceuster and Polfliet (2002), 17% of all Eurobonds are placed by a single bank and the rest are taken up by syndicates. Over 90% of syndicated issues are coordinated by a single leading bank. For particularly large issues (often exceeding one billion USD), two or three banks may share the book-running duties.

⁴ The primary document is the “term sheet” or “information memorandum” that is circulated to potential syndicate participants. The term sheet contains a short description of the borrower and an outline of the issue (coupon, maturity, suggested yield, fees, etc.). It also contains summaries of relevant financial information, plans for the use of proceeds, and agreements to be signed.

for the effort associated with selling the bonds, underwriters receive a fee and possibly a positive spread between the guaranteed and offering prices.

3. Expected Effects of the EMU on Bond Issue Costs

The EMU is expected to reduce the issue costs of European currency bonds for the following reasons.⁶ First, if the currency risk of the original constituent currencies was priced in the market (as argued by Dumas and Solnik (1995), Allayannis and Ihrig (2001) and De Santis and Gerard (1998)), then the elimination of this risk by the creation of a uniform currency should lead to a lower cost of capital. The EMU also improves risk-sharing opportunities, which may further reduce the cost of capital (Bekaert and Harvey (1995)).⁷ Indeed, using a multi-period APT model, Sentana (2002) finds that the European integration of the 1990's reduced the cost of capital for European firms. The reduction in the cost of capital is expected to lower the issue cost of Eurobonds, because both underpricing and underwriter compensation typically increase with the bonds' risk.⁸

Second, the adoption of the Euro may have reduced the degree of "home bias," which influenced European investors before the integration. Home bias, or the preference

⁵ According to Melnik and Plaut (1996), riskier bond issues are dealt with by increasing the number of underwriters (each receives a smaller allocation).

⁶ Smith and Walter (2000) and Santillan, Bayle and Thygesen (2000) discuss the expected impact of the introduction of the Euro on the money and bond markets.

⁷ Investment bankers often cite the reduction in price variability in the secondary market as a reason for preferring global issues over domestic offers. Price variability is driven by systematic as well as unsystematic risk. Selling debt securities to foreign investors could make them less sensitive to domestic systematic risk. On the other hand, it may increase the issuer's exposure to foreign market shocks (e.g. large changes in foreign interest rates).

⁸ The uncertainty associated with the market value of bonds increases with their risk. High uncertainty implies greater effort in estimating the value of the bonds and higher underwriting risk, both leading to larger underwriter compensation. High uncertainty also implies greater probability of insufficient demand, which could induce underwriters to underprice the issue.

of investors for financial assets with familiar characteristics, is an important factor influencing investment decisions (see Lewis (1999) for a review). In the context of the pre-EMU European financial markets, home bias was augmented by restrictive regulations. Before the EMU, most European pension funds were constrained by regulators to invest no more than 20% of their funds in foreign currency denominated assets. With the introduction of the Euro, such restrictions were practically abolished. The reduction in the degree of home bias has expanded the investor base for European currency bonds, and is therefore expected to reduce underwriter compensation and underpricing.⁹

Third, the integration of financial markets in Europe is likely to attract non-European investors to the new Euro-denominated assets. As the Euro substituted the legacy currencies, European financial markets have become more liquid and offer lower transaction costs for investors. These changes have made Euro-denominated bonds more attractive for non-European investors who would like to diversify their portfolios.¹⁰ Consequently, the effort and risk associated with selling Euro-denominated bonds (compared with bonds denominated in the legacy currency) have declined, which is expected to lead to lower underwriter compensation and smaller underpricing.

Fourth, before the introduction of the Euro, issuers of bonds denominated in a legacy currency had to select a syndicate with sales expertise in that currency. Thus, underwriting syndicates frequently included local banks to enhance the marketability of

⁹ According to Hartmann, Maddaloni and Manganelli (2003), the introduction of the Euro has created a more homogeneous market and as a result expanded the demand for Euro denominated bonds.

¹⁰ The importance of broad and liquid secondary market is discussed in Johnson (1994) and Kool (2000). According to McCauley (1997) and Hartman (1998), the preference of issuers for USD denominated bonds in the pre-EMU era was due to the lower transaction cost and greater liquidity of these instruments.

the bonds, which may have increased the issuance costs. The introduction of the Euro reduced the reliance on local expertise and therefore may have reduced the issue cost of Euro-denominated bonds.

Fifth, by creating a uniform currency, the EMU allows issuers to consolidate issues that otherwise would have been denominated in different currencies. To the extent that economies of scale exist in the underwriting industry (Altinkilic and Hansen (2000)), this effect should also lead to lower issue costs.

Consistent with these hypothesized effects, Santos and Tsatsaronis (2003) find that the introduction of the Euro currency caused a significant reduction in bond underwriting fees. We examine two additional components of issue costs: underwriter spread (the difference between the offering price and the guaranteed price to the issuer), and underpricing (the difference between the market price and the offering price) and, as discussed below, find interesting interactions among the three cost components. We next discuss the measurement of cost components and issue characteristics.

4. Variables Measurement

In the process of issuing fixed-coupon Eurobonds, there are three prices that merit attention. First, the syndicate guarantees a given price to the issuer. This guaranteed price (P_G) represents the gross proceeds to the issuer (i.e., before deducting the fee). The second price, which is determined by the syndicate several days later, is the offering price (P_O). At this price the underwriters are usually able to sell the entire issue. The third price is the market price after trading commences (P_M). Using these three prices and the

underwriter fee (FEE), we calculate the total issue cost and its components as detailed below.¹¹

Measured relative to the market value of the bonds, the total cost to the issuer (i.e., the percentage of the bonds' value that the issuer loses) is

$$\begin{aligned} \text{COST} &= \frac{\text{FEE} + P_M - P_G}{P_M} = \frac{\text{FEE}}{P_M} + \frac{P_M - P_O}{P_M} + \frac{P_O - P_G}{P_M} \\ &= \text{RFEE} + \text{UNDERPR} + \text{SPREAD} . \end{aligned}$$

RFEE denotes the relative fee. UNDERPR represents the implicit cost associated with underpricing, that is, the loss to the underwriter (and indirectly to the issuer) that results when the underwriter sells the bonds below their market value. SPREAD reflects the difference between the offer price to the public and the amount the underwriter passes on to the issuer, and therefore represents an indirect payment to the underwriter. Unlike the fee, however, the spread may be negative. Total underwriter compensation (COMP) is

$$\text{COMP} = \frac{\text{FEE}}{P_M} + \frac{P_O - P_G}{P_M} = \text{RFEE} + \text{SPREAD} .$$

In addition to the price and fee information, we obtain data on the issue size (AMOUNT, measured as the total nominal face value and expressed in millions of USD), years to maturity (MATUR), the credit rating of the issue, and the number of syndicate members (UNDERWR).¹² Using the credit rating information, we construct a credit

¹¹ The issuer has to bear some additional indirect costs such as accounting, legal and printing, which we do not consider due to data unavailability.

¹² We obtained very similar results to those reported below when measuring AMOUNT, MATUR and UNDERWR in logarithm form.

quality indicator (DQ), which takes values between one (lowest quality) and five (highest quality).¹³

5. Sample Characteristics and Descriptive Statistics

5.1 Before the EMU

We begin our investigation by comparing the issue costs of dollar denominated bonds with those of bonds denominated in three of the main legacy currencies that became part of the Euro: German Marks (GM), French Francs (FF) and Dutch Guilders (DG). These currencies are the three most important constituents of the European Currency Union (by weight).¹⁴ Our sample covers the period from September 1996 to October 1997, which preceded the market integration process mandated by the Maastricht Treaty. During this period, a relative stability existed in the secondary market, as bond yields generally declined for all currencies.

In order to increase homogeneity and facilitate across-currency comparisons, we focus on fixed-coupon bonds. We sample 316 issues, which represent approximately 20%

¹³ The corporate bonds rating are by S&P and Moody's (in the few cases where the ratings were not identical, we follow Jewell and Livingston (1998) and average them). The top rank is assigned to AAA or Aaa (DQ = 5). The second group includes the group of AA+ and AA or Aa1 and Aa2 (DQ = 4). The third group includes the rating AA- and A+ or Aa3 and A1 (DQ = 3). The fourth rank includes the group of A and A- or A2 and A3 (DQ = 2). The final group covers the BBB range or the corresponding Baa (DQ = 1). In a similar way we rank sovereign debt, most of which is issued by governments of stable western countries. Government of countries such as France, Germany, UK, USA and a handful of others routinely receive the highest rank by all rating firms. In our sample, the sovereign debt of such countries receives the top rank (DQ = 5). Debt issues of other countries are assigned rankings of 4, 3, and 2 depending on the relevant group. The ranking is based on the average score assigned by three rating organizations, which generally view "country risk" as being composed of three primary components: political risk, economic risk and financial risk. A lucid explanation of how sovereign risk ranking is constructed is contained in Erb, Harvey and Viscanta (1996). All the results reported in the next section are insensitive to the use of individual dummy variables for the different ratings instead of the multinomial DQ variable.

¹⁴ The designated weights of the European Currency Union basket were 31.9% for the German Mark, 20.3% for the French Franc, 12.5% for the British Pound, and 9.9% for the Dutch Guilder. However, the British Pound was not merged into the new currency.

of all relevant issues during the sample period.¹⁵ The currency denominations of these bonds are: 201 USD, 68 DM, 23 FF, and 24 DG. All issues were internationally underwritten and placed by syndicates whose members are primarily large international financial institutions. Table 1 presents summary statistics by currency denomination for the issue costs variables (total cost, underpricing, total underwriter compensation, underwriter fee, and underwriter spread) and issue characteristics (maturity, amount, number of underwriters, and credit rating). For each variable, we report the mean, median and standard deviation. For the DG, GM and FF bonds, we also report for each variable the *t*-statistic associated with the difference between the mean value of the variable for that currency and the value for the USD bonds ($t(\Delta)$).

The average issue costs of USD bonds are only about 0.32% of the bonds' market value. For the GM and FF bonds, the costs are 0.56% on average, significantly larger than for USD bonds. For the DG bonds, the issue costs are 0.42%, slightly and insignificantly larger than for USD bonds.¹⁶ The average issue costs across all the legacy currency bonds is 0.53%, which is about two-third larger than the average issue costs for USD bonds (*t*-statistic for the difference is 2.92). Thus, the issue costs of bonds denominated in the legacy currencies are both economically and statistically larger than the issue cost of USD bonds.

¹⁵ The data set was provided by a major investment bank out of the list of "participation offers."

¹⁶ These figures may be compared with domestic costs of large debt floatation. For example, Lee, Lochhead, Ritter and Zhao (1996) report that the cost of selling large issues of straight bonds is 0.64%. The larger scale and high credit quality in the international bond market may explain the smaller issue costs in our sample. Evidence on the effects of scale and credit rating on the issue costs is provided by many studies, including Livingston and Miller (2000), Smith and Walter (2000), Altinkilic and Hansen (2000), Cantor and Packer (1995) and Livingston, Pratt and Mann (1995).

The differences in total issue costs between the legacy currency bonds and USD bonds are not due to differences in underwriter compensation, as indicated by the insignificant $t(\Delta)$ values of COMP for the DG, GM and FF bonds. Rather, they are due to differences in underpricing: During the pre-EMU period, USD bonds were sold in the primary market at prices close to their market values (the mean value of UNDERPR for USD bonds is -0.02%), while the legacy currency bonds were sold at statistically significant discounts, ranging from 0.11% (GM bonds) to 0.16% (DG bonds).

Interestingly, the average values of the components of total underwriter compensation for the legacy currency bonds and USD bonds are very different. The mean fees for the legacy currency bonds are considerably larger than for USD issues, while the spreads are smaller by a similar magnitude. Consequently, the differences in total underwriter compensation between the legacy currency bonds and USD bonds are substantially smaller than the corresponding differences in underwriter fee. For both groups of bonds, however, the mean fee is large while the spread is negative (that is, the price guaranteed to the issuer is set above the offering price). We return to this issue below.

The mean size of USD-denominated issues is 345 million dollars, which is larger than the mean size of GM (316 million) and DG bonds (244 millions), but is similar to the size of FF bonds (344 million). When considering all legacy currency bonds as one group, the difference in issue size relative to USD bonds is insignificant (t -statistic of -1.23). USD bonds have average maturity of less than five years, while the legacy currency bonds have average maturities ranging between seven and ten years. The differences in maturity between the legacy currency bonds and USD bonds are all highly

significant. In addition, for the overall sample of legacy currency bonds, the average number of underwriters per issue is larger than for USD bonds (t -statistic of 2.11). The statistically significant differences in maturity and number of underwriters between the legacy currency bonds and USD bonds suggest that the former were more difficult to sell: Legacy currency bonds required a larger number of underwriters to place and had longer maturity, reducing the need to access the market frequently.

5.2 After the Completion of the EMU

The EMU sample includes 198 observations: 83 issues of USD denominated bonds, and 115 of Euro denominated bonds.¹⁷ Table 2 provides descriptive statistics for the variables. Total issue costs of both USD- and Euro-denominated bonds are 0.43% on average. For the USD bonds, this figure represents an increase relative to the pre-EMU period, while for the European currency bonds it represents a decline. Unlike the legacy currency bonds in the pre-EMU period, the Euro-denominated bonds are not underpriced, which is the primary reason for the decline in the issue costs of these bonds. Total underwriter compensation for the European currency bonds has not changed substantially; it was 0.40% prior to the EMU (average across all legacy currency bonds), and it is 0.38% after the completion of the EMU. For the USD bonds, total underwriter compensation has increased by an insignificant amount of 0.06% to 0.40%. Thus, both underwriter compensation and underpricing (and therefore total issue costs) are similar

¹⁷ The sample centers on the first ten months of 2002. During 2002, there were 664 straight fixed rate dollar denominated issues with maturity of more than 2 years, and 642 similar issues denominated in Euro. We sample 114 USD issues and 125 Euro issues, representing 17.2% and 19.5% of the population, respectively. 31 USD denominated issues and 10 Euro bonds were deleted due to missing costs, credit rating or syndicate data. The final sample includes 83 USD-denominated bonds and 115 Euro-denominated bonds.

for Euro- and USD-denominated bonds. This evidence suggests that the EMU has reduced the issue costs European currency bonds.

While total underwriter compensation is similar for Euro- and USD-denominated bonds, the composition of compensation is different: Underwriter fee (spread) is on average smaller (larger) for Euro-denominated bonds compared with USD bonds. This stands in sharp contrast to the pre-EMU period, when the average underwriter fees (spreads) of legacy currency bonds were larger (smaller) than those of USD bonds. Thus, consistent with the evidence in Santos and Tsatsaronis (2003), we find that the introduction of the Euro resulted in a considerable decline in underwriter fees for Euro-denominated bonds. However, this decline was offset by a corresponding increase in underwriter spread, leaving total underwriting compensation unchanged. In contrast to Santos and Tsatsaronis (2003), therefore, our results do not indicate that the EMU led to a sizeable decline in total underwriter compensation. Issue costs have indeed declined, but this was due to the elimination of underpricing rather than to a reduction in underwriter compensation. Evidently, the Euro-denominated bond market is more efficient than the market for bonds denominated in the legacy currencies, and underwriters offer newly issued bonds at prices close to market prices.

Turning to the issue characteristics, we find that the differences in characteristics between the USD- and Euro-denominated bonds in the EMU period are insignificant. In particular, the average issue size, maturity, credit quality and number of underwriters are all similar for the two groups of bonds. In the pre-EMU period, the European currency bonds had substantially longer maturity and larger number of underwriters than USD bonds. Thus, the EMU appears to have mitigated the factors causing differences in the

preferred characteristics of European currency issues relative to USD bonds. The changes in the characteristics of European currency bonds (shorter maturity, smaller number of underwriters) are consistent with the hypothesis that the EMU has reduced the risk and effort associated with issuing these bonds.

6. Regression Analysis

6.1 Primary Results

The differences in issue costs between the European currency bonds and USD bonds documented in the previous section could be due to differences in issue characteristics. To address this possibility, we next conduct a regression analysis that allows us to control for differences in characteristics. Table 3 presents the results of regressing the components of issue costs on a qualitative variable that indicates whether the issue is denominated in a European currency ($\text{NON\$} = 1$) or not ($\text{NON\$} = 0$), controlling for three issue characteristics: time to maturity, amount, and credit quality. Panel A (Panel B) presents the results for the pre-EMU (EMU) period. The dependent variables are total issue cost (COST), underpricing (UNDERPR), total underwriter compensation (COMP), underwriter fee (RFEE), and underwriter spread (SPREAD). As discussed in more detail below, the regression results are generally consistent with the findings from the univariate analysis (in Section 5), indicating the differences in issue costs between the European currency bonds and USD bonds can not be attributed to differences in issue characteristics.

For the pre-EMU period (Panel A), total issue cost of bonds denominated in legacy currencies are 0.168% larger than for USD-denominated bonds with similar

characteristics, as measured by the coefficient on NON\$. Given that the mean issue costs of USD bonds for the pre-EMU period is 0.32%, the incremental cost associated with issuing bonds denominated in a legacy currency was clearly substantial. The results of the underpricing regression indicate that this issue cost differential is due primarily to underpricing. The coefficient on NON\$ in the underpricing regression is positive and significant, and its magnitude is only slightly smaller than in the total cost regression. The third regression indicates that total underwriter compensation (COMP) is insignificantly related to currency denomination. In contrast, the two compensation components are strongly related to currency denominations. Compared with USD bonds, the fee for legacy currency bonds is considerably larger and the spread is smaller, even after controlling for issue characteristics. We return to this issue below.

The results for the EMU period (Panel B) indicate that the issue costs of USD- and Euro-denominated bonds are generally similar, as the NON\$ indicator variable is insignificant in the total issue cost, underpricing, and total compensation regressions. The compensation component regressions, however, reveal that underwriter fee (spread) is smaller (larger) for Euro-denominated issues compared with USD-denominated bonds. This result stands in sharp contrast to the pre-EMU period, when the fee for legacy currency bonds was substantially larger than for USD bonds and the spread was smaller.

6.2 Trade-off between Components of Underwriter Compensation

Melnik and Nissim (2003) document a strong trade-off between the fee and spread components of underwriter compensation for USD-denominated Eurobonds. They further show that this fee-spread structure is due to income tax minimization by issuers

and to strategic behavior by underwriters.¹⁸ To examine whether this trade-off also holds for European currency bonds, we re-run the spread regression including underwriter fee as an additional explanatory variable. To the extent that underwriters or issuers have preferences for a particular form of underwriter compensation, the fee, which is determined before the spread, may help to predict the spread.

Table 4 presents the regression results. In both periods, the coefficient on the fee is negative and highly significant, suggesting that underwriters set the fee and the guaranteed price (which determines the spread) strategically, so that one component offsets the other. The magnitude of the fee coefficient is similar across all regressions, and the coefficient on NON\$ is insignificant in both periods. These results suggest that the trade-off between the fee and spread is not affected by currency denomination. Thus, while the fee varies across currency denomination and over time, the spread co-varies inversely with the fee leaving total underwriter compensation rather constant.

6.3 Pooled Regressions

Next we re-run the regressions using all observations (from both periods) and including qualitative variables to capture the average effects of (1) the change in time period (EMU, equal to one for the EMU period and zero for the pre-EMU period), (2) denomination in a legacy currency (LEGACY, one for denomination in a legacy currency and zero for all other denominations), and (3) denomination in Euro (EURO, one for denomination in Euro and zero for all other denominations). The regression results are

¹⁸ Borrowers may postpone tax payments by minimizing spreads and increasing fees. They may therefore offer to pay higher up-front fees (which are tax-deductible faster than the spread) in return for a significant reduction in spreads. Underwriters may agree to this structure because their tax obligations are not sensitive to the combination. In addition to the tax motivation of issuers, the trade-off between the fee and spread may be due to a two tier-pricing mechanism that underwriters use to separate borrowers according to their expected total amount of borrowing. Melnik and Nissim (2003) provide evidence consistent with both hypotheses.

reported in Table 5. As shown, total issue costs (COST) is larger for bonds denominated in a legacy currency, increases with maturity, declines with credit quality, and is insignificantly related to the time period, issue denomination after the completion of the EMU, and issue amount.

The next two regressions (UNDERPR and COMP) confirm that the incremental issue costs associated with denomination in a legacy currency is due to underpricing, as LEGACY is significant in the UNDERPR regression but not in the COMP regression. In fact, total underwriter compensation (COMP) is insignificantly related to all three qualitative variables (EMU, LEGACY and EURO), suggesting that there is little variation over time and across currency denomination in underwriter compensation. In contrast, the fee regression (RFEE) reveals a substantial reduction in the average fee between the two periods (the coefficient on EMU is negative and highly significant), which is offset by a similar increase in the spread (the coefficient on EMU in the SPREAD regression is positive and highly significant). All of these findings are consistent with the results of the previous analyses, demonstrating the robustness of the findings with respect to alternative test specifications.

6.4 Syndicate Size

To the extent that the market for European currency bonds in the pre-EMU period was smaller and less liquid than the market for USD bonds, underwriters were likely to form larger syndicates when selling legacy currency bonds compared with USD bonds. If the arrival of the Euro increased the liquidity of European currency bonds and broaden their investment base, the difference in the number of underwriters per issue between European currency bonds and USD bonds is likely to be smaller in the EMU period. To

examine these hypotheses, we regress the number of underwriters per issue on the qualitative variables described above (EMU, LEGACY, and EURO), controlling for issue characteristics.

Table 6 presents the results. As expected, the number of underwriters is positively related to the issue amount and maturity (a proxy for interest rate risk), and negatively related to credit quality. The coefficient on EMU is negative and highly significant, indicating that the number of underwriters per issue has declined after the completion of the EMU. This decline applies to all currency denomination, but is particularly large for European currency bonds (the difference between the coefficients on LEGACY and EURO in the pooled regression is positive and significant). The overall decline in the number of underwriters is consistent with the strong consolidation trend in this industry during the late 1990s and the beginning of the millennium.¹⁹ The incremental reduction in the number of underwriters for Euro-denominated bonds is consistent with the positive effect of the EMU on the marketability of Euro-denominated bonds.

7. Summary and Conclusions

This study compares the issuance costs of Eurobonds denominated in USD and European currencies before and after the completion of the EMU in 2002. We find that the introduction of the Euro significantly reduced the issue cost of Euro-denominated bonds compared with bonds denominated in the legacy currencies. The reduction in issue

¹⁹ During the five-year period from 1997 to 2001 there were close to fifty major mergers in the industry. Some of the most visible mergers were Morgan Stanley with Dean Witter, Bankers Trust with Deutsche Bank, SBC Warburg with UBS, PaineWebber with UBS, Robertson Stephens with BankAmerica, Bank of America with NationsBank, BankBoston with Fleet Financial Group, Oppenheimer with CIBC Wood Gundy, Salomon with Smith Barney, Schroders with SSB Holdings, BZW with ABN-AMRO Holding, Donaldson Lufkin & Jenrette with CSFB, and JP Morgan with Chase Manhattan Corp.

cost was not due to a decrease in underwriter compensation, but rather to the elimination of underpricing. After the completion of the EMU, there was a substantial reduction in the underwriter fee of Euro-denominated bonds and a similar increase in the underwriter spread. The net effect on underwriter compensation was insignificant. The strong trade-off between the fee and the spread, which has been documented for USD-denominated bonds in the pre-EMU period, existed for bonds denominated in the legacy currencies as well, and continues to exist after the EMU for both USD- and Euro-denominated bonds. We also find that the EMU has changed the characteristics of Euro-denominated issues, particularly maturity and syndicate size, consistent with its expected effects on liquidity, investor base and transactions costs.

Med is the median, StD is the standard deviation, and $t(\Delta)$ is the t -statistic associated with the difference in the mean value of the variable between the European currency bonds and the USD bonds. The issue cost variables are measured relative to the market value of the issue after trading commences, and are expressed in percentage points. COST is total issue costs. RFEE is the underwriter fee. SPREAD is the indirect component of the underwriter compensation, that is, the difference between the offering price and the price guaranteed to the issuer. COMP is the sum of RFEE and SPREAD. UNDERPR is underpricing, that is, the difference between the market price and the offering price by the underwriter. MATUR is the number of years to maturity on the issue date. AMOUNT is the amount issued in millions of U.S. dollars (for non-USD issues, amount is multiplied by the exchange rate on the date of issue). UNDERWR is the number of underwriters. DQ is a debt quality measure that receives values between 1 and 5, where 5 is the highest grade and 1 is the lowest grade.

* The number of observations for UNDERWR is 168, 18, 60 and 17, respectively.
